1 Before the PI

1.1 Schrödinger, Heisenberg & interaction

We denote $U = \exp(Ht/i\hbar)$, and similarly with $H_0 \rightarrow U_0$, $V \rightarrow U_V$.

Schrödinger

1. State kets are $|\psi(t)\rangle = U |\psi(t=0)\rangle$;
2. observables are $A(t) \equiv A(t=0)$;
3. base kets are defined by $A|a\rangle = a|a\rangle$, therefore $|a(t)\rangle \equiv |a(t=0)\rangle$.

Heisenberg

1. State kets are $|\psi(t)\rangle \equiv |\psi(t=0)\rangle$;
2. observables are $A(t) = U^\dagger A(t=0)U$;
3. base kets are $|a(t)\rangle = U^\dagger |a(t=0)\rangle$.

Interaction We denote by a subscript S or I objects in the Schrödinger or interaction system. In the

1. State kets are defined as $|\psi(t)\rangle_I = U_0^\dagger |\psi(t)\rangle_S$;
2. observables are defined as $A_I(t) = U_0^\dagger A_S U_0$;
3. as base kets we use eigenstates of H_0 : $H_0 |n\rangle = E_n |n\rangle$. These evolve like $|n(t)\rangle = U_0 |n(t=0)\rangle$.

Then, we can generically write the evolution of a Schrödinger ket as

$$|\psi(t)\rangle_S = \sum_n c_n(t) \exp(E_n t / i\hbar) |n\rangle, \quad (1)$$

therefore the evolution of the interaction ket is

$$|\psi(t)\rangle_I = U_0^\dagger |\psi(t)\rangle_S = \sum_n c_n(t) |n\rangle. \quad (2)$$

We can write an equation for the evolution of the $c_n(t)$:

$$i\hbar \dot{c}_n(t) = \sum_m V_{nm} \exp(i\omega_{nm}t) c_m(t), \quad (3)$$

where $\omega_{nm} = (E_n - E_m)/\hbar$ and $V_{nm} = \langle n| V |m\rangle$. This is a matrix equation for the coefficient vector.

Time-dep perturbations If we define the interaction-picture evolution operator as $|\alpha, t\rangle = U_I(t) |\alpha, 0\rangle$ we have its evolution as $i\hbar \partial_t U_I = V_I U_I$.

For small times $U_I \approx \mathbb{1}$, so we can integrate the Schrödinger equation:

$$U_I = \mathbb{1} + \frac{1}{i\hbar} \int_0^t V_I(t') U_I(t') dt' \quad (4a)$$

$$= \mathbb{1} + \frac{1}{i\hbar} \int_0^t V_I(t') \left(\mathbb{1} + \frac{1}{i\hbar} \int_0^{t'} V_I(t'') U_I(t'') dt'' \right) dt' \quad (4b)$$

$$= \mathbb{1} + \frac{1}{i\hbar} \int_0^t V_I(t') dt' + \frac{1}{(i\hbar)^2} \int_0^t \int_0^{t'} V_I(t') V_I(t'') dt' dt'' + o(V_I^2) \quad (4c)$$

Now, if we start on a base ket $|i\rangle$, the evolution coefficients $c_n(t)$ will be given by the matrix elements $\langle n| U_I(t) |i\rangle$. We can compute these to any order in V_I , by taking the components of the previous equation and applying the following computation any time we have the components of V_I :

$$\langle n| V_I |i\rangle = \langle n| U_0^\dagger V U_0 |i\rangle = \exp(i\omega_{ni}t) V_{ni}, \quad (5)$$

since the $|n\rangle$ are eigenstates of the unperturbed Hamiltonian.

1.2 The propagator

If $H |\alpha'\rangle = \alpha' |\alpha'\rangle$, then the evolution operator can be decomposed as

$$U(t) = \sum_{\alpha'} \exp\left(\frac{E_{\alpha'} t}{i\hbar}\right) |\alpha'\rangle \langle \alpha'|. \quad (6)$$

This can be written in the position basis as a Green function by contracting with two position vectors:

$$\langle x' | U(t) | x'' \rangle = \sum_{\alpha'} \exp\left(\frac{E_{\alpha'} t}{i\hbar}\right) \langle x' | \alpha' \rangle \langle \alpha' | x'' \rangle \stackrel{\text{def}}{=} K(x', x''; t), \quad (7)$$

and with this we can directly compute the evolution at a generic time: $\psi(x'', t) = \int d^3x' K(x'', x'; t) \psi(x')$. It is effectively the transition amplitude: $K = \langle x'', t | x', 0 \rangle$ when seen in the Heisenberg picture (since we are evolving a base ket).

1. $K(x', x'', t)$ satisfies the Schrödinger equation, since it is a sum of terms which do;
2. $\lim_{t \rightarrow 0} K(x', x'', t) = \delta^3(x', x'')$.

1.3 Some useful propagators

Free particle We consider $H = p^2/2m$; the momentum eigenstates are $p |p'\rangle = p' |p'\rangle$, and they are also energy eigenstates with $H |p'\rangle = ((p')^2/2m) |p'\rangle$.

We compute:

$$K(x', x'', t) = \int dp' \langle x'' | p' \rangle \langle p' | x' \rangle \exp\left(\frac{(p')^2 t}{i\hbar 2m}\right), \quad (8)$$

and recall that $\langle x | p \rangle = \exp(-px/i\hbar) / \sqrt{2\pi\hbar}$. We simplify the exponent to get a Gaussian integral: it is known that

$$\int_{\mathbb{R}} dx \exp(-i\alpha x^2) = \sqrt{\frac{\pi}{i\alpha}}, \quad (9)$$

therefore in the end we get:

$$K(x', x'', t) = \frac{1}{2\pi\hbar} \exp\left(\frac{im(x'' - x')^2}{2\hbar t}\right) \sqrt{\frac{2m\pi\hbar}{it}}, \quad (10)$$

which for $t \rightarrow 0$ is in the form $\exp((x' - x'')^2/t) \sqrt{t} \rightarrow \delta(x'' - x')$.

Harmonic oscillator We consider $H = p^2/2m + m\omega^2 x^2/2$. It is known that the eigenfunctions are given by the Hermite polynomials:

$$\langle x' | n \rangle = \frac{1}{\pi^{1/4} \sqrt{2^n n!}} \frac{1}{x_0^{1/2}} H_n y \exp\left(-\frac{(x/x_0)^2}{2}\right), \quad (11)$$

where $x_0 = \sqrt{\hbar/(m\omega)}$ (both masses and frequencies are inverse lengths in natural units!). We also know the eigenenergies, $E_n = \hbar\omega(n + 1/2)$. We can then compute away, to finally get:

$$K = \sqrt{\frac{m\omega}{2i\pi\hbar \sin(\omega t)}} \exp\left(\frac{im\omega\left((x'')^2 + (x')^2 \cos(\omega t) - 2x'x''\right)}{2\hbar \sin(\omega t)}\right). \quad (12)$$

2 The Path Integral

We can time-slice the interval between a certain time $0 = t_0$ and another time $t = t_N$ in N parts. Then, evolving the system with a the propagator for each one, we get:

$$K(x_N, x_0, t) = \int \left(\prod_{i=1}^{N-1} dx_i \right) \left(\prod_{i=0}^{N-1} \langle x_{i+1}, t_{i+1} | x_i, t_i \rangle \right). \quad (13)$$

We call the time-slice $\epsilon = t/N$. We will expand the in ϵ up to first order the evolution operator $\exp(H\epsilon/i\hbar)$.
